**ABSTRACT** 

Data mining is a combination technology for analyze a useful information from

dataset using some technique such as classification, clustering, and etc. Clustering is one

of the most used data mining technique these day. Its application used as for image

segmentation, bioinformatics, and pattern recognition. . K-Means and K-Medoids is one of

clustering algorithms that mostly used because it's easy implementation, efficient, and also

present good results.

Besides mining important information, the needs of time spent when mining data

is also a concern in today era considering the real world applications produce huge volume

of data. This research analyzed the result from K-Means and K-Medoids algorithm and

time performance using another knowledge area known as High Performance Computing

(HPC) Cluster to parallelize K-Means and K-Medoids algorithms and using Message

Passing Interface (MPI) library. The results shown than K-Means algorithm gives smaller

SSE than K-Medoids. And also parallel algorithm that used MPI gives faster computation

time than sequential algorithm.

Keywords: Clustering, K-Means, K-Medoids, HPC Cluster, MPI
