ABSTRACT

cloud computing is a computing model that makes information and technology resources such as servers, middleware, and applications accessible via the Internet at any time as a service that can be used in public or private. cloud computing should be accessible and can run well without experiencing disorders such as server down and the other is therefore necessary to monitor the performance of the server so that it can determine the performance of the server. When a server goes down it will reduce its performance, so that the application is running can not be accessed. if not immediately addressed, there will be many problems that will occur and reduce the function of the server. This monitoring can also help an administrator where the task is to manage a network administrator, network repair in case of problems with the monitoring server then the task of the administrator will be lighter.
