

ABSTRACT

Plastic waste is a major problem in many countries, including Indonesia. One way to utilize plastic waste, in this case polyethylene terephthalate (PET) plastic, is to convert it into fuel oil using pyrolysis reactor. Controlling the temperature of a pyrolysis reactor is usually done manually. In this work, a temperature controller for a pyrolysis reactor is designed based on proportional, integral and derivative (PID) method. The reactor, as the plant in a closed loop control system, is heated with electric power and the PID controller is implemented to adjust the voltage level to the electric heater. By controlling the temperature, the pyrolysis furnace is expected to be able to be optimized in producing fuel oil from PET.

Keywords: pyrolysis, fuel oil, plastic Polyethylene Terephthalate (PET), PID, temperature control
