**ABSTRACT** 

Inter-Satellite Link (ISL) is a technology that allows communication between one

satellite to another satellite. ISL become one important part in the development of satellite

networks. There are several examples of previous missions using multiple satellites with the

aim of making the satellite constellation. One crucial part of the system of multiple satellite

while in orbit is how can the system communicate with the others, because the information

must be shared.

The ISL system required a device used for the transmission medium, an antenna.

Designed antenna should have a circular polarization to overcome the effects of faraday

rotation that will lead to polarization loss factor (PLF), because rotation ions contained in the

atmosphere. In this final project will be designed a microstrip antenna proximity coupled with

the addition of elements in the corners of radiating circular polarization to be generated that

will be used on a micro-satellite communications.

Designed antena is simulated with the help of the software simulator and realized with

FR-4 Epoxy materials with a value  $\varepsilon r = 4.3$  and h = 1.6 mm. Antenna working in 2.4 GHz band

(S-Band).
