**ABSTRACT** 

In an easy time, many activities are demanded to facilitate everything

quickly and easily. Some activities can be carried out easily without human

intervention. Like to take pictures or to monitor a situation can use a drone. Drones

or often called Unmanned Aerial Vehicle (UAV) are unmanned aircraft that fly by

being cont*Roll*ed by a computer or remote control.

One of the advantages of a drone is a drone that can fly in all directions.

With these advantages, drones can replace distant places easily by air. One of the

support of a drone that can be applied is that the drone can monitor from a distance.

Many types of drones depend on the number of propellers used. The more number

of propellers, the bigger the size and load that the drone can carry.

Therefore, at the end of this assignment, I will discuss a drone that will be

able to beat ± 2Kg stably and can land automatically over the river. Automatic

Landing is the mission of automatic drones to be able to land to a surface that has

been determined uncont Rollably by humans. This study uses ultrasonic sensors to

determine the distance between drones and surfaces.

Keywords: Drone, Automatic Landing, Ultrasonic Sensor
