ABSTRACT

In this study, adsorbent synthesis was carried out using silica from lemongrass ash. The results of the silica extraction are then mixed with Al₂O₃, NaOH, and H₂O to be synthesized into adsorbents. The resulting sample was characterized for crystallinity and bonding using XRD and FT-IR. The lemongrass, which hade been calcinated at 600°C within 3 hours, were subsequently mixed with 0.6 grams of SiO₂, 0.13 grams of Al₂O₃, 6.75 grams of H₂O and 0.97 grams of NaOH, as well as was incubated for 1 hour, has the highest specific adsorbtivity of 2583 mg/g. The results of XRD and FT-IR analysis showed that the adsorbent did not have sufficient zeolite material characteristics. However, its ability to reduce the salinity of seawater is far exceeded the ability of activated natural zeolites.
