

ABSTRACT

RSCM Medical Rehabilitation Hospital is a national referral hospital that plays an important role in physical, mental, and functional rehabilitation services. However, the results of observations showed several interior problems, such as less than optimal spatial layout, inadequate ramp facilities on emergency stairs, and medical equipment arrangement that interferes with circulation. Redesign is needed to create a functional, comfortable environment that supports patient recovery and the efficiency of medical personnel. The objectives of the redesign include improving patient comfort, spatial efficiency, meeting modern hospital design standards, increasing accessibility, and strengthening the visual identity and educational function of the hospital. Research methods include observation, documentation, interviews, precedent studies, and literature studies to provide a strong basis for producing an optimal design. Problems such as lack of ramp facilities, untidy arrangement of medical equipment, and inefficient spatial layout are the main obstacles. These problems indicate the need for redesign efforts to improve the quality of space, both in terms of functionality and aesthetics, in order to create a more optimal rehabilitation environment.
