

ABSTRACT

The multipath fading phenomenon is one of the main characteristic in wireless system that could decrease the performance and capacity of the system. To solve this problem, a simple system that provide good performance is needed. Layer, a new system implemented into MIMO is basically the strategy of symbol delivery on the transmitter antennas to solve the multipath fading problem. This system offers a better performance and capacity on the bad channel condition.

This Final Assignment analyses the performance of *Layer MIMO*, where on this system has 3 layers that will be compared the performance. These *Layer MIMO* are modelled into *Rayleigh* distributed mobile propagation channel, in correlated and uncorrelated condition with different user's speed.

The result of simulation shows that to reach BER 10^{-4} on the correlated channel with $0,1 \lambda$ spacing, need E_b/N_0 compensation about $1 - 7.1$ dB, 0.5λ spacing need E_b/N_0 compensation about $0 - 4.6$ dB, 1λ spacing need E_b/N_0 compensation about $0.1 - 3.1$ dB.
