

ABSTRACT

To increase the capacity in satellite transmission system, it can be done by dual-polarization technique in transmitter antenna and receiver antenna. So, with this technique the capacity can be increased into double capacity than single polarization only.

The problem which happens with dual-polarization technique is, cross-polarization effect or there are interferences which cross each other which is caused by molecules in the atmosphere when the information signals are transmitted to the receiver. Molecules in the atmosphere which cause cross-polarization are raindrops and ice crystals.

Independent Component Analysis (ICA) method is used to separate information which is mixed together into independent information so the detection error can be solved. In this final project, a simulation will be made which can measure ICA performance to improve satellite link performance.

In this software implementation, Independent Component Analysis (ICA) method will be expected to solve cross-polarization in satellite link. In this final project, it will also use the FastICA algorithm to speed up computation for separating mixed signals. The evaluation results of this simulation will measure Cross-Polarization Discrimination (XPD) value, Cross-Polarization Isolation (XPI) value of that dual-polarization, Auto-correlation between sources and the convergence time of the FastICA algorithm.
