

ABSTRACT

Huge chance for inconsistency data in single system caused by crash. To solve the problem a method is made which usually called database recovery. A future in DBMS that very useful.

ARIES and Shadow Paging are two of the recovery algorithms that famously use nowadays to solve the problem of system crash in DBMS. Each of them has advantages and disadvantages that becomes a plus factor for each method. It needs to be compared so we can get an assumption about both of the recovery algorithms.

This final task will compare two recovery algorithms those are ARIES and Shadow Paging by simulate them. The simulator will be made using Delphi as the programming tool and hopefully the simulator can be useful learning tool.

Key words:

DBMS, database recovery, ARIES, shadow paging, simulation, Delphi
