

Abstract

Validation is a good validation of the structured layer either from the client/user and from the server. In practice before the data in the form to tell the server will filter out javascript and send the data to the server when the data are correct, and this is called the validation of the client / user. Then on the server is (eg: PHP) is also doing the same as validation javascript before data entry into the database.

There are enough of the theory of making the above javascript (client side) and PHP (server side) should do the same validation. The solution here is the javascript does not function as a validation inputan but serve only as an introduction to the process data to PHP with AJAX method so the user does not have to wait page loading ago, when the user disabled javascript then the process must still take place despite loading the page. Solutions such as the tools to do this is with the help of plugins jQuery Ajax Form.

With AJAX using the jQuery javascript library on the file sharing web application using PHP as server-side script, it will be AJAX-based web application that can be reduce the flow data.
