

ABSTRACT

The need for Internet connections increased along with the variation of devices in the market which can be used to explore in the virtual domain. Web server is an access service provider to the user via Hypertext Transfer Protocol (HTTP) over the files contained on a web site. Due to the increasing number of user requests to a web server for the files contained on a web site, it needs a load balancer to distribute the load on two or more access lines so there will not be a centered connection to only one network device.

This load balancer technology uses Nginx web server. Nginx is one piece of software for the server due to the high performance, stable, having lots of features, easy to configure, and using only few resources on the server.

This final project will be implemented in a network that consists of a load balancer server, web server and database server using a Virtual Private Server (VPS). The result will be a network that can serve the files contained on the website to divide the load that wants to access to the multiple servers, so it will not be centered to only one network device.

Keywords: *Web server, load balancer, Nginx, VPS*
